Objective: Patients with metastatic tumors are most frequently expressed with painful spinal lesions. However, effective palliative treatment is still controversial. The aim of this study is the assessment of the efficacy and safety of vertebral augmentation in conjunction with radiofrequency ablation (RFA) of painful spinal metastases.

Materials and Methods: Twenty-six patients with metastatic spine tumors treated with RFA in conjunction with cement augmentation between June 2014 and December 2019 were retrospectively analyzed. The patients were followed up for an average of 25.2±13.8 months. Evaluation of efficacy is performed based on tumor pain, pain disability, functional activities, quality of life, neurological status, and tumor progression. Reliability evaluation was made based on complications and side effects.

Results: The mean age was 64.4±12.6 years. The female to male ratio was 14:12. RFA with augmentation was successfully performed on all patients. No major complications developed in these patients. Primary tumors were observed to be more breast (38%), renal (23%) and multiple myeloma (12%). Visval analogue Scale scores decreased after the procedure and improvement continued in every period of follow-up (from 8.2±1 months preoperatively to 3.5±1.6 months postoperatively p<0.005). The patients discontinued painkiller use after one month. On the Oswestry dysability scale score, significant improvement was observed in the first month (41.8±15.1 vs 82.6±9.1, p<.005). Tumor progression was observed in different regions in 10 patients and we lost those patients in the follow-up.

Conclusion: In painful spinal metastases with preserved posterior wall and pedicle integrity, the combination of RFA in conjunction with vertebroplasty can be safely implemented for pain palliation and local tumor control.

INTRODUCTION

Spine involvement is known to be about 40% in patients with the metastatic bone disease⁽¹⁾. Clinically, this problem, which may lead to severe pain, pathological fractures and neuromuscular dysfunction, causes the patient to become immobile and leads to a deterioration in the quality of life⁽²⁻⁴⁾. Palliative treatment in these patients poses major challenges and calls for a comprehensive, multidisciplinary approach⁽⁵⁾. In painful metastatic lesions, radiofrequency ablation (RFA) therapy has begun to be used as a micro-invasive process, which disrupts intraosseous nerve fibres, reduces lesion volume, reduces osteoclastic activity, and prevents pain transmission by disrupting tumor cells that produce nerve stimulating cytokines^(6,7).

At the same time, the combined use of cement to increase the resistance of the spine to compressive loads can increase the

quality of life of the patients and prevent complications that may lead to neurological damage resulting from pathological fractures^(8,9).

This study aimed to investigate the effect of combined treatment of percutaneous RFA and vertebral augmentation on the quality of life of patients with spinal metastasis.

MATERIALS AND METHODS

After the approval of the University of Health Sciences Turkey, Antalya Training and Research Hospital Clinical Research Ethics Committee (date: 22.12.2020, number: 20/23), the data of patients who underwent RFA and vertebral augmentation for painful metastatic spine disease in our clinic between 2014 and 2019 were retrospectively analyzed. The database included the patien's age, gender, primary tumor histology, level of the treated spine, the location and volume of the lesion in the involved spine, the number and duration of ablations performed

and the patient's history of radiotherapy in the previous six weeks. After a complete description of the study to the subjects, written informed consent was obtained. The Declaration of Helsinki were taken into account during the present study.

Patients undergoing RFA and vertebroplasty were selected according to the decision of the council consisting of a spine surgeon and medical oncologist. Patients who have pain that leads to decreased quality of life and could not be controlled with conventional analgesics, localized tumors in two or three adjacent vertebrae and persistent and recurrent pain despite radiation therapy were included in the study. Patients with osteoblastic lesions, spinal instability and cord compression due to metastatic mass were excluded from the study.

After the patients were turned to the prone position under superficial sedation, the surgical area was disinfected with Betadine solution and prophylactic antibiotic treatment was administered before and after the procedure (cefazoline IV, 1 g x 4/12 hours). Local anaesthetic infiltration was applied, starting from the skin area, including the vertebral periosteum to be treated. The unilateral or bilateral transpedicular guide was placed under the guidance of fluoroscopy (Figure 1)⁽¹⁰⁾. A transpedicular biopsy was performed before performing RFA as a routine protocol and the results were recorded on the patient chart (Figure 2). After the procedure, analgesic treatment was ordered by the routine protocol of the clinic. Patients were

evaluated at the first week and the first, third, and sixth months in the postoperative period with the Visual analogue scale (VAS) and the Oswestry disability index (ODI) for the assessment of the quality of life, and as well as with an magnetic resonance imaging in terms of recurrence.

RESULTS

Data of 26 patients with painful spinal metastases who met the inclusion criteria were retrospectively analyzed. The mean age of the patients was 64.4±12.6 years. Female to male ratio was 14:12. The demographic characteristics of the patients are presented in Table 1. The most common primary tumor was Breast Ca, followed by Renal Ca and Multiple Myeloma. It was observed that the treated metastatic spine disease was in the thoracic region in 35% of the cases and the lumbar

region in 65%. RFA with vertebroplasty was successfully performed on all patients (Figure 3 and 4). Cement leakage was not observed. No other complications occurred during the procedure. There was a significant decrease in the VAS scale after the procedure, indicating a decrease in pain intensity and a significant difference in each post-procedure compared to the pre-procedure. The evaluation of the ODI at 1 month compared with before the procedure also showed significant improvement in all domains (Table 1). Analgesic doses were reduced in all patients 24 hours after the procedure, and one month later all patients had greatly improved their quality of life and stopped the analgesic because there was no significant pain that would affect functional activity. Nine of the 26 patients (34.6%) enrolled in the study had tumor progression in different regions, and all of these patients died during a mean follow-up period of 19 months (range: 6-40 mos.). No local recurrence was observed in the radiographic examinations performed during the controls of the patients.

DISCUSSION

In this study, we retrospectively evaluated the efficacy and safety of RFA in conjunction with vertebral augmentation in pain palliation in painful spinal metastases. As a result of the evaluation, we determined that this treatment approach is effective and safe. During the follow-up period, no recurrences, major side effects, or complications were observed, and

secondary surgical interventions were not required. All pain was effectively controlled using only analgesics. The patients' quality of life improved. This study supported the use of RFA in conjunction with vertebroplasty as a viable, minimally invasive spinal approach for the treatment of patients with thoracolumbar vertebral metastasis. Our findings were supported by the literature.

Since RFA was first carried out of in conjunction with vertebroplasty there has been an increase in the literature investigating its role in painful spinal metastases(11). It has been emphasized that this treatment approach can be used not only for pain palliation but also for local tumor control. In the guidelines published by the Metastatic Spine Working Group, patients with asymptomatic spinal metastases, uncomplicated painful metastases, and stable pathological vertebral fractures and with a life expectancy of more than six months can safely have RFA and vertebral augmentation performed for pain palliation and local tumor control⁽¹²⁾. In their study, Hoffman et al.⁽¹³⁾ demonstrated that the application of vertebral augmentation with RFA had a 100% pain-relieving effect within the first 24 hours, and they found that the combined procedure had a synergistic effect. It was shown that VAS scores significantly decreased from 7.2/10 before the procedure to 3.4/10 after the procedure⁽¹³⁾. Reves et al.⁽¹⁴⁾ reported significant improvement in palliation of pain and level of function with combined RFA and vertebroplasty in their multicenter retrospective study of 49 patients with 72 painful vertebral metastases. In the studies, the most important common findings, apart from pain palliation, was that no treatment-related complications occurred during the procedure and follow-up.

In research studies, many reasons have been shown why RFA should be performed before vertebroplasty⁽¹⁵⁾. The most often reason given for this sequence is reducing the potential for distal metastasis in the venous system by changing the location of tumor cells, preventing complications associated with embolization by causing thrombosis of the vertebral venous plexus, and ensuring a more equal distribution of cement to provide better stability to the spine⁽¹⁶⁾. In addition, radiographic local control rates of combined RFA and vertebroplasty were reported as 89% (41/46) and 70% (21/30) after three months and one year, respectively⁽¹⁷⁾.

Nakatsuka et al.⁽¹⁸⁾ reported serious complications such as paraparesis and severe pain in up to 25% of patients after the RFA treatment for spinal metastases, but they stated that most of the patients they treated had a posterior wall and pedicle invasion and as a result related complications occurred at a high rate⁽¹⁸⁾. They reported that the symptoms disappeared during the follow-up. In our study, we did not see any major complications in the patients, since the spinal metastases did not destruct the posterior wall and the pedicles. We observed a significant improvement in pain and quality of life using the VAS and ODI scores that can accurately evaluate the refractory pain and quality of life of the patients. A limited number of patients, the absence of a control group, and a short follow-up

turkishspine

period are the limitations of our study. However, the emergence of many metastases in the follow-up of the patients poses a serious difficulty in the long-term follow-up to determine the recurrence and survival of these patients.

CONCLUSION

RFA with combined cement injection is safe and effective in the palliative treatment of patients with painful metastatic spine tumors.
